Prolog variables are similar to "unknowns" in algebra: Prolog tries to find values for the variables such that the entire clause can succeed.

Once a value has been chosen for a variable, it cannot be altered by subsequent code; however, if the remainder of the clause cannot be satisfied, Prolog may backtrack and try another value for that variable.

Swi-prolog.org is also kind enough to give a tutorial. The ones that I use are: `--goal`: This is basically to help prolog determine the exit code of the program.

Example Prolog Program

In Prolog, program components are understood as predicates. They may succeed or fail. To succeed/fail means that the system was/was not able to establish that the predicate holds given the information available. Success or failure is implemented in Python through generators.
